Sample Questions and Detailed Explanations from OCR Chemistry May 2013 F321

Below are typical questions from the exam along with comprehensive explanations to aid understanding.

Question 1: Nucleophilic Substitution in Halogenoalkanes

Question:

Explain why bromoethane reacts more slowly with aqueous potassium hydroxide than chloroethane. Include in your answer the factors affecting the rate of nucleophilic substitution.

Answer Explanation:

The rate of nucleophilic substitution in halogenoalkanes depends on the strength of the carbon-halogen bond and the ability of the halogen to leave as a leaving group.

- Bond Strength: The C-Br bond in bromoethane is weaker than the C-Cl bond in chloroethane because bromine is larger and less tightly held, making the bond easier to break.
- Leaving Group Ability: Bromide ions (Br^-) are better leaving groups than chloride ions (Cl^-) due to their larger size and greater polarizability, which stabilizes the negative charge once they leave.
- Reaction Rate: Since bromine's bond is weaker and its leaving group is more stable, bromoethane reacts more rapidly in nucleophilic substitution reactions compared to chloroethane.

Key Point: The combination of bond strength and the stability of the leaving group influences the rate; thus, bromoethane reacts faster than chloroethane under similar conditions.

Question 2: Aromatic Substitution

Question:

Describe the electrophilic substitution of benzene with a nitrating mixture and explain why benzene reacts more slowly than alkene with electrophiles.

Answer Explanation:

- **Reaction Conditions:** Benzene reacts with a mixture of concentrated nitric acid and sulfuric acid (the nitrating mixture) in the presence of a catalyst (H_2SO_4).
- **Reaction Mechanism:** The electrophile generated is the nitronium ion (NO_2^+). Benzene undergoes substitution, not addition, preserving its aromatic ring.
- **Reaction Rate:** Benzene reacts more slowly than alkenes because of its aromatic stability. The delocalized π -electron system in benzene is highly stable, and disrupting this stability requires significant energy. Therefore, electrophilic substitution occurs at a slower rate compared to the addition reactions of alkenes, which lose some of their π -bond character but are less stabilized overall.

Key Point: Aromaticity confers extra stability to benzene, which resists addition reactions, favoring substitution that preserves the aromatic system.
