## Quantum States in Semiconductor Nanostructures

### Quantum Confinement and Discrete Energy Levels

At the core of the unique properties of nanostructures lies quantum confinement. When the dimensions of a semiconductor are comparable to or smaller than the electron's de Broglie wavelength ( $\sim 10$  nm), the motion of electrons becomes restricted, leading to quantized energy levels akin to those in atoms.

This confinement results in:

- Discrete energy spectra: Unlike the continuous bands in bulk materials, nanostructures exhibit sharp energy levels.
- Size-dependent optical properties: The energy gap can be tuned by changing the size of the nanostructure, enabling customized optical responses.

For example, smaller quantum dots emit higher-energy (bluer) photons, while larger dots emit lower-energy (redder) photons—a property exploited in display technologies and bio-imaging.

### Electron and Hole States

Electrons in nanostructures populate quantized conduction band states, while holes (the absence of an electron in the valence band) occupy discrete valence band states. The interaction between these charge carriers determines the optical and electronic behavior of the nanostructure.

- Excitons: Bound states of electrons and holes generated upon optical excitation. Their energies are also quantized, influencing emission spectra.
- Coulomb interactions: Play a significant role in the behavior of excitons, especially in small quantum dots where confinement enhances Coulomb effects.
